Formation of Hydrazine from Inorganic Compounds.

Ber., 27, 3498-3499, 1894

J. Chem. Soc., V. 68, p. 74, 1895

Hydrazine is formed by the reduction of recently-prepared potassium dinitrosulphonate, $K_2SO_3H_2O_2$ with sodium amalgam at 0°, and is separated by treatment with benzaldehyde. Zinc dust and ammonium hydroxide or soda may also be used as the reducing agent; other substances which act in alkaline solution cause the formation of hydroxylamine, ammonia, and potassium hyponitrite in varying quantity, and the yield of hydrazine is consequently much diminished.

TITLE: Lifetimes in single crystals of gallium arsenide

SOURCE: Fizika tverdogo tela, v. 8, no. 10, 1966, 3047-3049

TOPIC TAGS: gallium arsenide, semiconductor single crystal, carrier lifetime, majority carrier, minority carrier, photoconductivity, temperature dependence, semiconductor laser

ABSTRACT: The lifetimes of majority and minority carriers in n-type single-crystal GaAs were determined by measuring the stationary-photoconductivity and photoelectromagnetic-effect voltages at a low injection level of the minority carriers. The lifetimes of the majority and minority carriers were determined separately from the plots of the short-circuit current of the photoelectromagnetic effect and the stationary-photoconductivity current with account taken of the capture of the carriers by traps. The mobility of the minority carriers was assumed equal to the mobility of the majority carriers, the latter being calculated from the Hall effect. The temperature dependence of the lifetimes was measured in the interval from 77 to 450K. The test procedure and the sample preparation are briefly described. The results showed that the lifetimes are sensitive to the presence of structural defects, since one

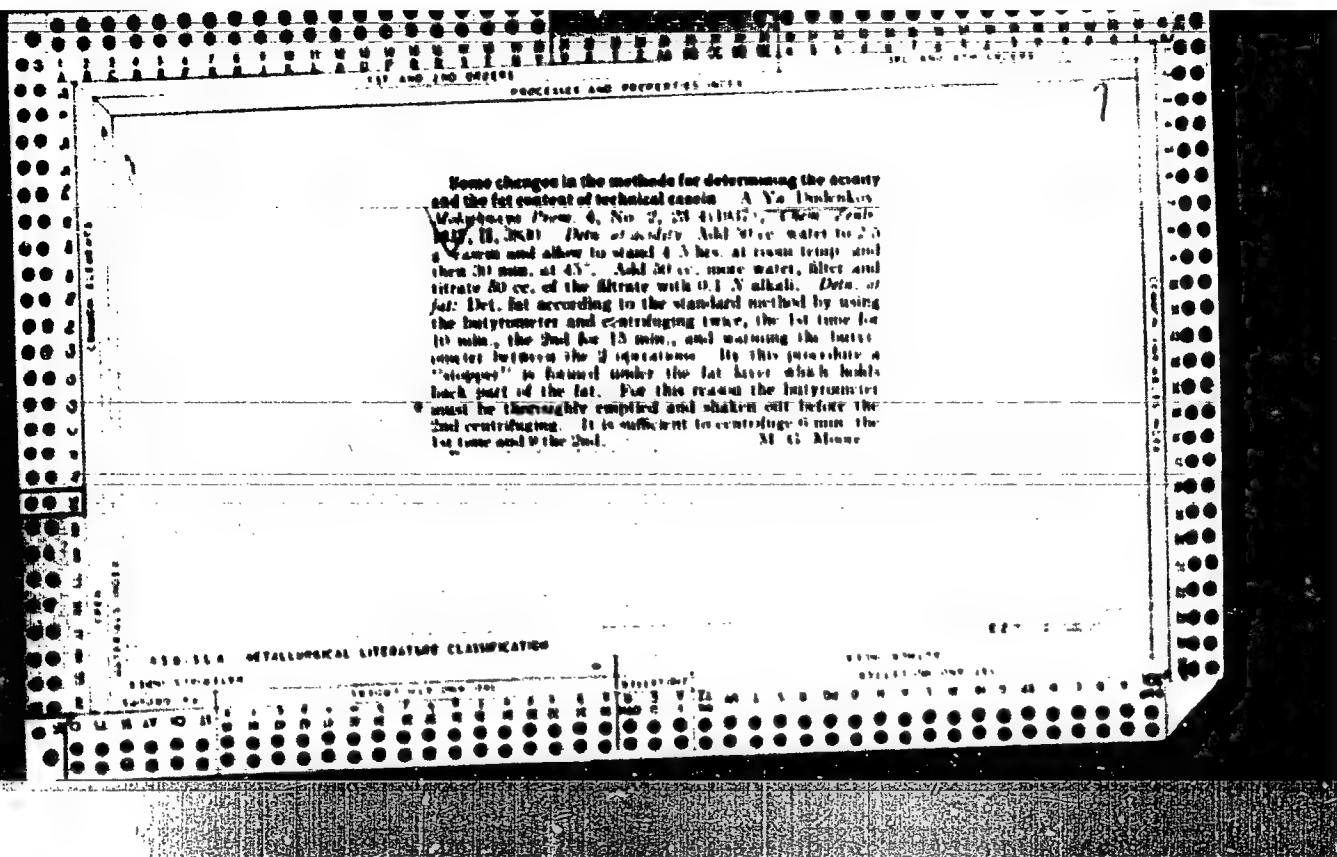

Card 1/2

ACC NR: AF6033568

sample with many defects exhibited a large difference between the lifetimes of the majority and minority carriers, as well as a large degree of trapping of the holes. A connection between the time characteristics obtained at low injection level and the emission characteristics of semiconductor lasers made of the same samples was also established. The authors thank P. G. Yelisseyev and Yu. M. Popov for a discussion of the experimental results and K. P. Fedosyev and V. P. Shchedrin for help with the work. Orig. art. has: 3 figures.

The grain method of casein production. A. L. Lankford
(Kerr Butter Trust). *Milk Industry Progress*, 11, No. 1, 20
11, 1930. Casein should be peptized at 35-40° for water
factory particle shape and size. The final pH in peptizer
should be about 4.2-4.8; a brief heating to 70-80° is
advisable after peptization; wash water should be neutralized by
addition of acid (usually the available water is slightly
alkaline). Washing must be adequate to remove all milk
sugar and thus reduce the possibility of bacterial decomposition
in storage. G. M. Kneeland

Methods of determination of fat in butter without a balance. A. Lyubimov (Kiev Butter Trust). *Molochays* *Prav.* 12, No. 3, 36-2 (1941).--The Merrens method, using *Amal* (*Ibid.* 9, No. 9, 1948), is poorly adapted for field use and gives erratic results unless precisely 40° temp. is maintained. The Godel method is much better and gives results that are on the av. within 0.33% of the usual gravimetric results. In it the sample (8 g.) is heated in a corked flask to 80°, centrifuged 3-5 min., heated 3-5 min. to 65° and the level of the upper and lower layers is read; computation is by a table.
